Abstract

How I created a BLAST app for Cyverse.

Install Cyverse SDK

1 If you haven't already, install the Cyverse SDK (<u>https://github.com/cyverse/cyverse-sdk</u>) so you have access to "jobs-submit" and such.

Create Github repo

2 I created <u>https://github.com/hurwitzlab/muscope-blast</u> to hold the code for the Stampede/Cyverse app.

Stampede apps are recommended (<u>http://developer.agaveapi.co/</u>) to have a 'stampede' directory for the code -- perhaps a different dir for each execution system?

I also created <u>https://github.com/hurwitzlab/ohana</u> for the code to build the BLAST dbs and such.

Create the BLAST dbs

3 I pulled down the HOT from Cyverse Data Store at /iplant/home/scope/data/delong/HOT224-238.

To ensure I had everything, I ran <u>https://github.com/hurwitzlab/ohana/blob/master/scripts/check-md5.pl6</u> to check against MD5 sums.

I wrote <u>https://github.com/hurwitzlab/ohana/blob/master/scripts/mk-blast.sh</u> to concatenate all contigs/genes/proteins files into one per type, then index with BLAST.

Load Eggnog annotation dbs

4 The original Eggnog annotations to the predicted genes were delivered in a format that spread one annotation over two lines, so I wrote https://github.com/hurwitzlab/ohana/blob/master/scripts/merge-genes.pl6 to merge them. As there were 15M annotations, I struggled over how to store and retrieve them. I wanted a database like MySQL or Pg, but it's unlikely I could bring up a daemon-based server on stampede, so I chose SQLite. Problem there is I was quite certain it would be too slow to put 15M in one table, so I decided to make a db for each sample (103 of

them). The script <u>https://github.com/hurwitzlab/ohana/blob/master/scripts/pyloader.py</u> will load the dbs.

Create entry script

5 This can be any language or executable, but I tend to write these in bash. I often call mine 'run.sh' (<u>https://github.com/hurwitzlab/muscope-blast/blob/master/stampede/run.sh</u>) and base it off a template (<u>https://github.com/kyclark/metagenomics-book/blob/master/bash/basic.sh</u>) that accepts named arguments. This script will query the input file(s) to the BLAST dbs and then use any resulting hits to predicted genes to query SQLite for annotations which will be placed into an additional file.

Create "test.sh"

6 The <u>https://github.com/hurwitzlab/muscope-blast/blob/master/stampede/test.sh</u> is for testing that the app is able to be submitted (via 'sbatch') to SLURM and will run.

Create "app.json"

7 The <u>https://github.com/hurwitzlab/muscope-blast/blob/master/stampede/app.jso</u>n file describes the app to Agave so it can be registered. It's most important to define the 'inputs' and 'parameters' with argument names that you will reference via environmental variables in the 'template.sh' script.

Create "template.sh"

8 The <u>https://github.com/hurwitzlab/muscope-blast/blob/master/stampede/template.sh</u> script will take the arguments from Cyverse as environmental variables defined in your 'app.json''s inputs/parameters. I usually just have this pass the arguments to 'run.sh'.

"files-upload" assets to execution system

9 Use 'files-upload' to put the app/scripts onto the storage (execution?) system. There is an 'upload' target in the Makefile for this. If you change just one file, you can upload that one e.g.

\$ files-upload -F run.sh kyclark/applications/muscope-blast-0.0.2/stampede

Anytime you change your code, test it locally and then "files-upload" the changes into Cyverse.

Register the app with "apps-addupdate"

10 Run "apps-addupdate -F app.json" to register the app with Agave.

Create "job.json"

11 Run "jobs-template \$APP > job.json" (e.g, just run "make jobs-template") to generate a JSON template for submitting the job via the Agave API.

Submit "job.json"

Use 'jobs-submit -F job.json' (or 'make jobs-submit') to test if it will submit. Use 'jobslist | head' to see the status. Your job will be the top one and will start off like 'PENDING' and then 'STAGING,' 'QUEUED,' 'RUNNING,' and then 'FAILED' or 'FINISHED.' Using the job ID (e.g., '5905387002803589606-242ac114-0001-007') with 'jobs-status' and 'jobshistory,' you can find out more about what it is doing, possibly where it is failing. When it is done, you can use 'jobs-output' to see what was created.

The results will land in your "\$WORK/<userid>/job-<jobid>-<jobname>" directory.

Submit job via DE

13 Use https://de.cyverse.org/de/ to find the job and submit there.
