ABSTRACT

The monocyte chemoattractant protein-1 (MCP-1/CCL2) is a member of the C-C chemokine family, and it is a potent chemotactic factor for monocytes.

dx.doi.org/10.17504/protocols.io.bktmkwk6

An anti-human monocyte chemoattractant protein-1 (MCP-1/CCL2) coating antibody is adsorbed onto the microwells by incubation overnight at 4°C with carbonate-bicarbonate buffer.
2 Add 50 µl of human serum or plasma into the wells. Human MCP-1/CCL2 present in the serum sample binds to antibodies adsorbed into the microwells.

3 The microplate is blocked with 3% non-fat milk-PBS buffer and later wash to remove unbound proteins.

4 Fifty (50) µl of biotin-conjugated anti-monocyte chemoattractant protein-1 (MCP-1/CCL2) antibody is added. The optimal dilution must be investigated.

5 The microplate is rewashed with PBS-Tween 20 buffer, pH 7.4.

6 One hundred µl of streptavidin-HRP conjugate is added and it binds to the biotin-conjugated anti-human MCP-1/CCL2 antibody.

7 The plate is washed following incubation to remove the unbound Streptavidin-HRP conjugate.

8 Add 100 µl of 3,3',5,5'-tetramethylbenzidine (TMB; Sigma-Aldrich) into each well.

9 Incubate the microwells in the dark for 15 min.

10 A colored product is formed in proportion to the quantity of MCP-1/CCL2 present in the sample or standard.

11 The reaction is terminated by addition of 100 µl 3M H2SO4 and the absorbance is measured at 450 nm.

12 A standard curve is made from 7 human MCP-1/CCL2 standard dilutions and the human MCP-1/CCL2 sample concentration is determined.

13 For better results place the microplate on a microplate shaker in every incubation.
