Protocol status: Working
This protocol has been successful for the three tested species, Nitzschia lecointei, Navicula perminuta, Fragilariopsis cylindrus CCMP1102. Cultures have been stable and uncontaminated for > 18 months (DAPI screening and no growth on BD Difco 2216 agar plates).

Abstract

Table 1. Antibiotic concentrations used for establishing axenic sea-ice diatom cultures.

	Antibiotic	Final concentration (µg/ml)
	Ampicillin	50
	Gentamycin	15
	Streptomycin	125
	Chloramphenicol	10
	Ciprofloxacin	10
	Penicillin	100

Axenic diatom protoc...

105KB

1 Pre-treat an optically dense diatom culture with 3 min of vortex-mixing (< 8°C) and 30 sec of ultrasonication (80% in 5-s pulses) on ice to remove attached bacteria from diatoms and EPS aggregates.

2 Centrifuge cells at 1000 × g for 10 min (< 8°C) and wash the pellet twice with sterile F/2 medium (Guillard, 1975) to remove the majority of loose bacterial cells.

3 Add six antibiotics to the medium according to Table 1 (see abstract), and incubate for 5 days at –1°C and under light (20–45 µmol photons m^{-2} s^{-1}).

4 Centrifuge cells at 1000 × g for 10 min (< 8°C) wash pellet in fresh F/2 medium.

5 Pick < 10 cells to start the axenic cultures (pipetting or plate on F/2 agar to pick single colonies).

6 After recovery and growth (~2 months), check for bacterial cells using DAPI staining and after agar plating on half-strength BD Difco™ Marine Agar 2216 (< 8°C), kept at seawater salinity using artificial seawater (411 mM NaCl, 9.39 mM KCl, 26.1 m M $MgCl_2 6H_2O$, 28.4 mM $MgSO_4 \cdot 7H_2O$, 5.01 mM TAPSO buffer).

7 If bacteria are still present, repeat protocol. Axenic cultures are usually established within the first or second attempt.
