Keywords: ont minion library preparation of uhmw gdna, uhmw gdna, parasitic nematode, ont minion library preparation, oxford nanopore technology, minion library preparation, dnatm magbead, single adult hookworm, dna, concentratortm magbead kit protocol, sequencing protocol, minion

Abstract

This custom protocol optimizes extraction, purification, and Oxford Nanopore Technologies (ONT) MinION library preparation for ultra-high molecular weight genomic DNA (uHMW gDNA) from parasitic nematodes. It can be used effectively with both low-input samples (e.g., a single adult hookworm) and high-input samples (e.g., a chunk of tissue from an Ascaris sp. adult).

Protocols on which this workflow is based:

- Zymo® Quick-DNATM Magbead Plus Kit protcol
- Oxford Nanopore Technologies® SQK-LSK-109 gDNA Ligation Sequencing protocol
- Zymo® DNA Clean & Concentrator Magbead Kit protocol (best-testing phase only)

Troubleshooting

Before start

- Add 1,040 μL Zymo Proteinase K Storage Buffer to each tube of Zymo Proteinase K (20 mg) prior to use. The final concentration of Proteinase K is ~20 mg/ml. Store resuspended Proteinase K at -20°C after mixing.
- For best results, allow AMPure XP beads (stored at 4°C) to come to RT prior to use.

Part 1: Ultra-HWM gDNA extraction | Zymo Quick-DNA HWM MagBead Plus Kit | ~3 hr

- 1 Set dry bath to \$\\\$ 55 \cdot \C
- 2 For each sample, add the following to a clean 1.5 mL microcentrifuge tube to create a master mix:

```
    Δ 95 μL
    Zymo DNA Elution Buffer Zymo Research Catalog #D3004-4-1
    Δ 95 μL
```

- Zymo Biofluid & Solid Tissue Buffer Zymo Research Catalog #D4081-3-25
 Δ 10 μL
 Zymo Proteinase K Zymo Research Catalog #D3001-2-20
- 2.1 Vortex the master mix gently to mix, then spin down and keep on ice
- 3 Using a new pipette tip or sterilized forceps, add one whole worm (or a piece of tissue) directly from tissue preservative to the bottom of a clean 1.5 mL microcentrifuge tube

Note

Transfer as little tissue preservative liquid as possible to the new tube during this process

- 4 Use a new NEB Monarch Pestle NEB Catalog #T3002-1 to grind and crush the tissue in the tube. Keep the pestle in the tube
- Add Δ 200 μ L master mix (prepared in Part 1 Step 2) to each tube containing tissue and pestle
- 6 Continue using the pestle to grind the tissue within the master mix until fully homogenized. Remove the pestle, being careful to keep any tissue in the tube by wiping the pestle on the tube edges as it is removed
- 7 Close the tube and mix by inverting and flicking gently, then spin down briefly to recollect tissue and liquids

Incubate sample in dry bath at \$\circ\$ 55 °C for \$\circ\$ 02:30:00 or until tissue solubilizes.

During incubation, flick tube every \$\circ\$ 00:20:00 to agitate tissues, then briefly spin down to recollect liquids and replace tube in dry bath

Note

If a very large amount of input tissue was used: It is likely there will still be visible tissue even after hours of lysis. If so, centrifuge the sample for 00:01:00 at

10000 x g or greater to pellet debris, then pipette all liquids into a new clean 1.5 μL microcentrifuge tube. (The majority of gDNA will be contained in the layer of liquid just above the pellet, so pipette carefully to get as much liquid as possible without disturbing the debris.) Discard the tube contain the pelleted debris and use the retained supernatant for Part 2.

Part 2: Ultra-HWM gDNA purification | Zymo Quick-DNA HWM MagBead Plus Kit | ~4 hr + overnight incubation

2h 20m

- 9 Set dry bath to \$\circ\$ 37 °C

Solution

Zymo Quick-DNA™ MagBinding Buffer

Zymo Research Catalog #D4077-1-150

each sample

- 11 Flick tubes to mix, then spin down briefly to recollect liquids

Note

MagBinding Beads settle quickly, so ensure beads are kept in suspension while dispensing by vortexing the beads $\underline{\text{each time}}$ before they are added to a sample

To ensure DNA binds to beads, mix on a rotator mixer at a low speed for 00:40:00 at Room temperature. Spin down briefly before proceeding with the next step

Y

Set sample tubes on a magnetic stand until beads have separated from solution, then remove and discard the supernatant. Remove sample tubes from the magnetic stand.

Note

Some beads may adhere to the sides of the tube. When removing supernatant, aspirate slowly to allow these beads to be pulled to the magnet as the liquid level is lowered.

- Flick to mix initially, then mix on a rotator mixer at a low speed for 00:20:00 at Room temperature. Spin down briefly before proceeding with the next step

20m

17 Set sample tubes on a magnetic stand until beads have separated from the solution, then remove and discard the supernatant. Remove sample tubes from the magnetic stand

Note

Some beads may adhere to the sides of the tube. When removing supernatant, aspirate slowly to allow these beads to be pulled to the magnet as the liquid level is lowered.

- 18 Add <u>Δ</u> 500 μL
- 19 Flick to mix, then spin down briefly
- Set sample tubes on a magnetic stand until beads have separated from solution, then remove and discard the supernatant. Remove sample tubes from the magnetic stand

Note

Some beads may adhere to the sides of the tube. When removing supernatant, aspirate slowly to allow these beads to be pulled to the magnet as the liquid level is lowered.

- 21 Add 4 900 μL X Zymo g-DNA Wash Buffer **Zymo Research Catalog** #D3004-2-200 to each sample
- 22 Flick to mix, then spin down briefly
- 23 Transfer the entire sample (all liquid and beads) to a new clean 1.5 mL microcentrifuge tube
- 24 Set samples (now in new tubes) on a magnetic stand until beads have separated from the solution, then remove and discard the supernatant. Remove sample tubes from the magnetic stand

Note

Some beads may adhere to the sides of the tube. When removing supernatant, aspirate slowly to allow these beads to be pulled to the magnet as the liquid level is lowered

- 25 Add 4 900 μL X Zymo q-DNA Wash Buffer Zymo Research Catalog #D3004-2-200 to each sample
- 26 Flick to mix, then spin down briefly
- 27 Transfer the entire sample (all liquid and beads) to a new clean 1.5 mL microcentrifuge tube
- 28 Set samples (now in new tubes) on a magnetic stand until beads have separated from the solution, then remove and discard the supernatant. Leave sample tubes on the magnetic stand

Note

Some beads may adhere to the sides of the tube. When removing supernatant, aspirate slowly to allow these beads to be pulled to the magnet as the liquid level is lowered

- 28.1 Use a P10 pipette to remove any residual liquid from the bottom of the tube
- Air dry the beads for up to 00:20:00 and proceed to next step once beads are dry, but not over-dry

20m

Note

It may take less time for the beads to dry, so check them often during this process. Beads will change in appearance from glossy black when still wet to a matte black/brown when fully dry. Over drying the beads may result in lower gDNA recovery.

- 30 Add Δ 50 μL S Zymo DNA Elution Buffer **Zymo Research Catalog #**D3004-4-50 to each sample and flick gently several times to mix. Spin down briefly
- Incubate in dry bath at \$\mathbb{\math

32 Incubate on bench top at Room temperature overnight.

After overnight incubation, set tubes on a magnetic stand until beads have separated from solution, then move the supernatant (now containing eluted gDNA) to a new clean 1.5 mL microgentrifuge tube

Note

The eluted DNA can be used immediately or stored at 4 °C or 4 -20 °C for future use

- 34 Use Δ 1 μ L of final elution to quantify extraction via Qubit analysis
- 35 Use 1 μL of final elution to assess fragment size distribution via TapeStation

Part 3: DNA repair and end-prep | Zymo Clean & Concentrator, ONT Ligation Sequencing, & NEBNext Companion Kits | ~1.5 hr

36 Set dry bath to \$65 °C

- 37 Defrost the needed NEB DNA and End Repair reagents on ice (see Part 3 Step 38)
- For each sample, add the following to a clean 0.2 mL PCR tube to create a master mix, pipetting 10–20 times between each addition to mix:

Δ 3.5 μL

🔀 NEBNext® FFPE DNA Repair Buffer New England Biolabs Catalog #E7180S

🔀 NEBNext FFPE DNA Repair Mix - 96 rxns New England Biolabs Catalog #M6630L

 $\stackrel{\hbox{\scriptsize Λ}}{=} 3.5~\mu L$

X NEBNext Ultra II End Prep Reaction Buffer New England Biolabs Catalog #E7647

Δ 3 μL

- X NEBNext Ultra II End Prep Enzyme Mix New England Biolabs Catalog #E7646
- 38.1 Keep master mix on ice
- Add \perp 12 μ L of master mix (prepared in Part 3 Step 38) from the PCR tube directly into each 1.5 mL microcentrifuge tube containing extracted & purified uHWM gDNA (from Part 2). Mix all components by gently flicking, and spin tubes down to recollect liquids

1h

the supernatant

- Briefly spin samples down briefly and transfer to magnetic stand to allow beads to pellet until solution is clear (1–2 min). With the tubes still on the magnet, pipette off and discard the supernatant
- Air dry the beads for 00:10:00

10m

Note

MagBinding Beads utilize a different chemistry than SPRI beads (e.g., AMPure XP beads) so there is not the same risk of over-drying. It is important for optimal elution that the residual buffer is completely removed/evaporated from the beads

- 51 Add Δ 50 μL S Zymo DNA Elution Buffer **Zymo Research Catalog** #D3004-4-10
- Manually agitate samples for 00:10:00 by gently flicking/inverting (and occasionally spinning dow to recollect liquids)

10m

Note

This volume is too small to be able to use most rotator mixers effectively, so manually agitation is necessary

- Briefly spin samples down and pellet the beads on a magnet until the eluate is clear and colorless (1–2 min)
- Remove and retain the Δ 50 μ L of eluate (containing repaired & end-prepped DNA) to a new clean 1.5 mL microcentrifuge tube
- Use $\perp 1 \mu L$ of final elution to quantify via Qubit assay

Part 4: Adaptor ligation and clean up | ONT Ligation Sequencing & NEBNext Companion Kits | ~3 hr + overnight incubation

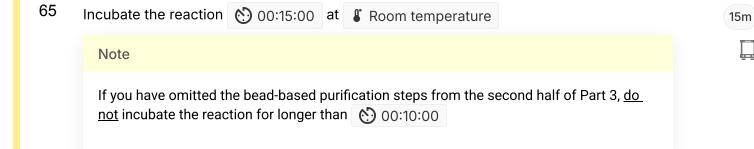

1h

56 57 Remove AMPure XP Beads Beckman Coulter Catalog #A63880 from storage at 58 Spin down ONT Adaptor Mix (AMX) Oxford Nanopore Technologies Quick T4 DNA Ligase New England Biolabs Catalog #E7180S and place on ice 59 Thaw ONT Ligation Buffer (LNB) Oxford Nanopore Technologies Room temperature , spin down, and mix by pipetting. Place on ice immediately after thawing and mixing 60 Thaw Elution Buffer (EB) Oxford Nanopore Technologies at Room temperature , vortex to mix, spin down, and place on ice 61 Thaw one tube each of Short Fragment Buffer (SFB) Oxford Nanopore Technologies and X Long Fragment Buffer (LFB) Oxford Nanopore Technologies Room temperature, vortex to mix, spin down, and place on ice 62 For each sample, add the following, in order, to a new clean 1.5 mL microcentrifuge tube, pipetting 10-20 times between each addition to mix: ONT Ligation Buffer (LNB) Oxford Nanopore Technologies Δ 25 μL **Quick T4 DNA Ligase New England Biolabs Catalog #E7180S** 🚣 10 μL ONT Adaptor Mix (AMX) Oxford Nanopore Technologies 62.1 Keep master mix on ice after mixing 63 For each sample, prepare 1:3 SFB:LFB titrated wash mix by adding the following to a new clean 1.5 mL microcentrifuge tube, and then vortex to mix:

Δ 125 μL	Short Fragment Buffer (SFB) Oxford Nanopore Technologies
Δ 375 μL	

- 63.1 Keep titrated wash mix on ice after vortexing
 - Pipette $40 \, \mu$ of master mix (prepared in Part 4 Step 62) directly into entire volume of repaired and end-prepped gDNA from Part 3. Mix all components by gently flicking and spin tube down to recollect liquids

Resuspend AMPure XP Beads Beckman Coulter Catalog #A63880 by vortexing and add 0.4X volume resuspended beads to each sample, then flick to mix

Note

AMPure XP Beads settle quickly, so ensure beads are kept in suspension while dispensing by vortexing beads <u>each time</u> before they are added to a sample

Note

Example for calculating 0.4X volume: If input is 89 μ L (after adding master mix), add 35.6 μ L AMPure XP Beads

- Mix on a rotator mixer at a low speed for 01:00:00 at Room temperature
- Spin down the sample and pellet on a magnetic stand. Keeping the tube on the stand, pipette off and discard the supernatant

1h

- Wash the beads by adding $\[\] 250 \ \mu L \]$ 1:3 SFB:LFB titrated wash mix (prepared in Part 4 Step 63). Flick the beads to resuspend, spin down, then return to the magnetic rack and allow the beads to pellet. Remove the supernatant using a pipette and discard
- Spin down the beads and place them back on the magnetic rack. Use a P10 pipette to pipette of any residual liquid and allow beads to air-dry for 00:00:30 to

2m 30s

Note

(?) 00:02:00

Do not allow the pellet of beads to dry to the point of cracking! Over-drying beads will result in reduced yields

- Remove the tube from the magnetic stand and resuspend the beads in Δ 15 μL Elution Buffer (EB) Oxford Nanopore Technologies
- Briefly spin down and incubate in dry bath at \$\mathbb{8}\$ 37 °C for \$\mathbb{O}\$ 02:00:00 . During incubation, flick tube every \$\mathbb{O}\$ 00:20:00 to agitate tissues, then briefly spin down to recollect liquids and replace tube in dry bath

2h 20m

Note

For HMW & uHMW gDNA, incubation at $37 \, ^{\circ}\text{C}$ for longer times can improve the recovery of long fragments

74 Incubate on the bench top at Room temperature overnight

- 75 1. After overnight incubation, pellet the beads on a magnet until the eluate is clear and colorless (at least 1 min)
- 76 Remove and retain the \perp 15 μ L of eluate (containing the prepared library) to a new clean 1.5 mL microcentrifuge tube
- 77 Use 🚨 1 μL of final elution to quantify library via Qubit analysis

Note

Note: For same-day or near-future sequencing, store the prepared library on ice or at 🖁 4 °C until ready to be loaded onto a flow cell. Otherwise, store libraries at

₿ -20 °C
