ABSTRACT

Purpose: Describe the parameters evaluated per FFPE human liver sample received/obtained for the University of Minnesota SenNet TMC. These parameters are used to evaluate whether the tissue can be characterized as "normal" vs "diseased" prior to further protocols.

Protocol status: Working
We use this protocol and it's working
1. Prepare two slides with serial sections of the FFPE liver sample – 1 section per slide.

2. Section A -- Stain with H&E.
Section B -- Stain with trichrome.

3. Mount coverslip.

4. Schedule evaluation with pathologist (ideally with a strong liver background).

5. Request assessment and record of the following scores:
   1. Steatosis, macro %
   2. Steatosis, score (0, 1, 2, 3)
   3. Ballooning (0, 1, 2)
   4. Inflammation (0, 1, 2, 3)
   5. Fibrosis (0, 1a, 1b, 1c, 2, 3, 4)
   6. Any comments on preservation/quality of the sample
   7. Other/Additional identifications (e.g. the presence of NASH or other disease states)
Record these values and consider them prior to moving the sample forward for experimentation processing.

Inventory and archive H&E and trichrome stains at room temperature – Can be scanned if future images are required.

Inventory and archive FFPE blocks at room temperature.
