Keywords: ChIP-seq, genomic regulatory network, characterization of genomic regulatory network, precise regulation of transcriptional program, in vivo genome, wide location of transcription factor, genome, genomic, seg experiment, transcription factor, chromatin accessibility, nascent transcription, transcriptional program, histone modification, chromatin immunoprecipitation, transcription, novel chip, regulatory network, chip, antibody, seq

Abstract

Understanding the precise regulation of transcriptional programs in human health and disease requires the accurate identification and characterization of genomic regulatory networks. Next-generation sequencing (NGS) technologies are powerful, and widely applied tools to map the in vivo genome-wide location of transcription factors (TFs), histone modifications, chromatin accessibility, and nascent transcription that make up these regulatory networks. While chromatin immunoprecipitation followed by sequencing (ChIP-seq) is one of the oldest, and most-utilized experimental techniques to study the location and abundance of TFs, experiments still frequently require optimization to reproducibly yield good data with high signal-to-noise ratios due to the massive variability between possible antibody-antigen combinations and commercial reagents.

To overcome these obstacles, we systematically carried out well over 500 ChIP-seq experiments designed to test every aspect of typical ChIP-seg experiments and developed rev-ChIP, a novel ChIP-seg method that is optimized for scalability, robustness, low-input, speed, cost efficiency and data quality. We find that rev-ChIP can be scaled to work for cell numbers ranging from millions to under a thousand, and from a single sample to 500 samples a week in a non-automated fashion with minimal hands-on time. Additionally, rev-ChIP has been tested on a variety of sample types ranging from cell lines to sorted primary cells and solid tissues.

Troubleshooting

Lysis and Sonication

1 Thaw cell pellet on ice and resuspend cells in $4500 \,\mu L$ of lysis buffer.

Note

1We do not recommend using $\perp 500 \mu$ of lysis buffer or tip sonication when sonicating less than 500K cells. In this case we suggest using Covaris (\perp 130 μ L) or PIXUL (\perp 60 μ L).

2 Sonicate samples for 7 cycles.

Note

This step is dependent on crosslinking method, and cell line or tissue type and should be optimized.

Note

Double crosslinked DNA is harder to sonicate and requires more rounds of sonication.

Note

Make sure not to oversonicate your samples and keep them constantly cold.

Expected result

Chromatin size range of 200-500.

Input Cleanup

- 3 Take \perp 10 μ L of each sample (for input) and put them into new PCR strip.
- 4 Dilute lysis buffer (LB3 - add 55ul 10% Triton X-100, Metivier - add 750ul Metivier Dilution Buffer, RIPA - None). If splitting lysates for IP, make sure diluted samples are well mixed. Split lysates as required if needed.
- 5 Add 🚨 68 µL of Elution Buffer (10mM Tris pH8, 0.5% SDS, 5mM EDTA, 280mM NaCl) + 🚨 1 μL RNase A to each input sample and incubate for 🔥 00:15:00 at 🖁 37 °C .
- 6 Add A 1 ul 55 of Proteinase K to each input sample and incubate at 8 55 °C for ♦ 01:00:00 and then at \$ 65 °C for ♦ 00:30:00 .

Immunoprecipitation

7 Prepare Dynabeads A/G: capture Dynabeads on magnet, remove supernatant and resuspend in equal volume of appropriate lysis buffer.

Note

For LB3 use LB3 + 1/9th volume of 10% Triton X-100, for Metivier use an equal volume of Metivier Dilution Buffer and for RIPA use an equal volume of RIPA buffer.

- 8 Add the appropriate volume of beads + antibody to each ChIP sample.
- 9 Incubate IP overnight on wheel at \$\mathbb{4} \cdot \C \quad \(\text{(rotating at 8rpm)}.

Input Cleanup

- 10 Create mastermix of \perp 2 μ L 1 SpeedBeads + \perp 120 μ L 120% PEG8000/1.5M NaCL (8.5% PEG, 1M NaCl), mix thoroughly, and add \perp 122 μ L of mastermix to each input sample.
- 11 Incubate at RT for 00:10:00 .
- 12 Wash 2x with Δ 200 μ L of 80% EtOH on magnet (move strip side to side 10x slow, 10x fast).

Note

We suggest using a repeater pipette here to speed things up.

Note

If magnet not available we suggest vortexing beads.

13 Air-dry until cracks appear on bead pellet.

Note

Air-drying should take approximately 00:14:00.

14 Elute in \perp 15 μ L TT (0.05% Tween 20, 10mM Tris pH 8.0, cold).

Note

We suggest using a repeater pipette here to speed things up.

Note

Washes

15 Add 100x PIC to WBI/III and TET ($\stackrel{\bot}{\bot}$ 10 μ L PIC per $\stackrel{\bot}{\bot}$ 1 mL WBI/WBIII/TET). Do 3x washes with \perp 180 μ L \mid WBI + PIC, 3x washes with \mid 180 μ L \mid WBIII + PIC, and 2x washes with \perp 185 μ L cold TET + PIC.

Note

We suggest using a multichannel pipette here to speed things up.

Note

The addition of PIC (Protease Inhibitor Cocktail) is not required, but highly recommended.

16 Resuspend beads in \triangle 25 μ L of cold TT using repeater pipette.

Library Preparation

17 Collect beads and take 🚨 2 μL of each input supernatant (1-2ul for 500K cells) that will be library prepped and add \perp 23 μ L of TT to each input taken.

18 Create a mastermix of \perp 1.5 μ L of Enzyme Mix End Prep + \perp 3.5 μ L of End Prep Reaction Buffer per sample, mix well and add $\Delta 5 \mu L$ of mastermix to each sample. Incubate for (5) 00:30:00 at \$ 20 °C and then (5) 00:30:00 at \$ 65 °C .

- 19 Add \perp 1 μ L of Bioo ChIP Adaptors (10.625 μ M) to each sample.
- 20 Create a mastermix of \perp 15 μ L Ligation Master Mix + \perp 0.5 μ L of Ligation Enhancer per sample, mix well, and add \perp 15.5 μ L of mastermix to each sample and incubate for (€) 00:15:00 at \$\mathbb{8}\$ 20 °C .

- 21 Create a STOP solution mastermix of \perp 4 μ L 10% SDS + \perp 3 μ L 0.5M EDTA + \perp 20 μ L water per sample and add \perp 27 μ L of mastermix to each sample.
- 22 Add \perp 4.5 μ L of 5M NaCl to each sample.

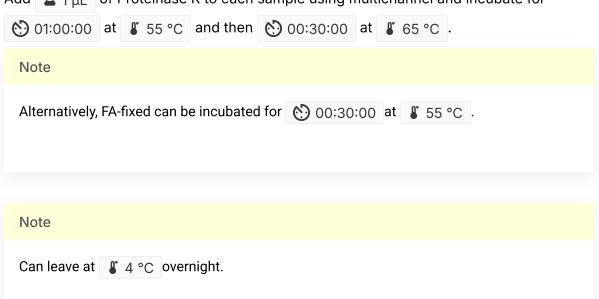

Note

We recommend using a multichannel to speed things up.

Proteinase K and Reverse Crosslinking

23 Add 🚨 1 μL of Proteinase K to each sample using multichannel and incubate for

Cleanup

24 Create mastermix of \perp 2 μ L SpeedBeads + \perp 61 μ L 20% PEG8000/1.5M NaCL (8.5% PEG, 1M NaCl), mix thoroughly, and add \perp 63 μ L of mastermix into new tube strips, then collect and transfer the supernatant of samples into these new tubestrips with \triangle 63 μ L of speedbeads + peg.

Note

DO NOT MIX PROTEIN A/G BEADS WITH SPEEDBEADS

25 Incubate at RT for 6000:10:00 .

26 Wash 2x with \perp 200 μ L of 80% EtOH on magnet (move strip side to side 10x slow, 10x fast).

Note

We recommend using a repeater pipette to speed things up.

27 Air-dry until cracks appear on bead pellet.

Note

Air-drying should take approximately 00:14:00.

28 Elute in Δ 25 μL TT (0.05% Tween 20, 10mM Tris pH 8.0, cold). Collect beads on magnet and transfer supernatant into new PCR strips.

Note

We recommend using a multichannel to speed things up.

Library Prep Amplification PCR

29 Do PCR.

Mastermix Library PCR		
25.5ul MM + 24.5ul sample	1x	20x
Sample	24.5	
(Blue Cap) NEBNext Ultra II Q5 2x MM	25	500
100uM Solexa 1GA	0.25	5
100uM Solexa 1GB	0.25	5

PCR Program		
	98°C	30 seconds
R	98°C	10 seconds
60°C	15 seconds	
72°C	30 seconds	
	72°C	1 minute
	4°C	ON

Final Cleanup

- 30 \perp 40.5 μ L of mastermix to each sample.
- 31 Incubate at RT for 👏 00:10:00 .
- 32 Wash 2x with Δ 200 μ L of 80% EtOH on magnet (move strip side to side 10x slow, 10x fast).

Note

We recommend using a repeater pipette to speed things up.

33 Air-dry until cracks appear on bead pellet.

Note

Air-drying should take approximately 00:14:00.

34 Elute in $\stackrel{\square}{=}$ 20 μL of TT.
