ABSTRACT

This protocol is for comparing two different samples at the transcript level, using long reads that are mapped to transcripts.

Input(s): stranded fastq files (see steps 1-8 of [Stranded Mapping from Long Reads](#)), transcript reference fasta file, annotation file

Output(s): transcript table, sorted by differential coverage, annotated with gene name / description / location

BEFORE START INSTRUCTIONS

Obtain a transcript fasta file, and an annotation file. For the mouse genome, I use the following files:

1. Transcript [CDS] sequences from [Ensembl](#); [this file](#) is the most current at the time this protocol was created.
2. Annotation file obtained from [Ensembl BioMart](#) (Ensembl Genes -> Mouse Genes) as a compressed TSV file with the following attribute columns:

- Transcript stable ID
- Gene description
- Gene start (bp)
- Gene end (bp)
- Strand
- Gene name
- Chromosome/scaffold name

Index Preparation

1 Prepare transcript index (see Guidelines for data sources)

```
lastdb Mus_musculus.GRCm38.cds.all.fa <(zcat  
Mus_musculus.GRCm38.cds.all.fa.gz)
```

2 Prepare barcode adapter index

```
barcode_base.fa
```

```
lastdb -uNEAR -R01 barcode_base.fa barcode_base.fa
```

3 Prepare cDNA adapter index

```
adapter_seqs.fa
```

```
lastdb -uNEAR -R01 adapter_seqs.fa adapter_seqs.fa
```

Read Correction

4 Collate basecalled reads into separate files for pass and fail (but all barcodes thrown together)

```
pv workspace/fail/*/*.fastq | gzip > called_fail.fastq.gz  
pv workspace/pass/*/*.fastq | gzip > called_pass.fastq.gz
```

5 Correct collated reads with canu (v1.8+). To make sure that all reads are considered, the genomeSize parameter should be set to about 1/20 of the total number of uncorrected bases.

```
canu -correct overlapper=minimap genomeSize=400M \  
minReadLength=100 minOverlapLength=30 -p canu_corrected -d  
canu_corrected -nanopore-raw ./called_pass.fastq.gz \  
./called_fail.fastq.gz
```

6 Identify corrected reads using [fastx-length.pl](https://github.com/typhloids/fastx-length.pl)

```
~/scripts/fastx-length.pl <(pv
canu_corrected/canu_corrected.correctedReads.fasta.gz) | \
awk '{print $2}' | gzip > corrected_readNames.txt.gz
```

- 7 Extract uncorrected reads using [fastx-fetch.pl](#)

```
pv called_fail.fastq.gz called_pass.fastq.gz | ~/scripts/fastx-
fetch.pl -v -i corrected_readNames.txt.gz | gzip >
uncorrected_all.fastq.gz
```

- 8 Join corrected and uncorrected reads. The uncorrected reads are converted to fasta format with [fastq2fasta.pl](#) to make the joined file formats consistent.

```
pv uncorrected_all.fastq.gz | zcat | fastq2fasta.pl | gzip >
uncorrected_all.fasta.gz
pv uncorrected_all.fasta.gz
canu_corrected/canu_corrected.correctedReads.fasta.gz | zcat | \
gzip > uncorrected_corrected_all.fasta.gz
```

Demultiplexing

- 9 Map *uncorrected reads* to barcode sequences to generate CSV file of assignments. Canu v1.8 is very good at trimming off repetitive adapter sequences (including barcodes).

```
lastal -Q 1 -P 10 barcode_base.fa <(pv called_*.fastq.gz | \
zcat) | ~/scripts/maf_bcsplit.pl | \
gzip > barcode_assignments_all.csv.gz
```

- 10 Map *uncorrected reads* to adapter sequences to generate CSV file of assignments.

```
lastal -Q 1 -P 10 adapter_seqs.fa <(pv called_*.fastq.gz | \
zcat) | ~/scripts/maf_bcsplit.pl | \
gzip > adapter_assignments_all.csv.gz
```

- 11 Create 'wide' table indicating barcode/adapter assignments. This R script creates files 'barcode-adapter_assignments_ideal.csv.gz' and 'barcode-adapter_assignments_valid.csv.gz'.

```

#!/usr/bin/env Rscript
bc.df <- read.csv('barcode_assignments_all.csv.gz');
ad.df <- read.csv('adapter_assignments_all.csv.gz');

library(dplyr);
library(tidyr);

## Create table of adapter additions
ad.tbl <- group_by(ad.df, query, target, dir) %>%
  summarise() %>%
  unite(tdir, target, dir, sep='.') %>% mutate(present=TRUE) %>%
  spread(tdir, present);

## collapse multiple query/target pairs into one
bc.tbl <- group_by(bc.df, query, target) %>%
  summarise(dir=paste(unique(dir), collapse='/'));
bc.wide <- spread(bc.tbl, target, dir);

## identify reads with a unique barcode
bc.unique.tbl <- group_by(bc.tbl, query) %>% summarise(n = n()) %>%
  filter(n == 1) %>% select(-n) %>% left_join(bc.tbl,
by='query') %>%
  left_join(ad.tbl, by='query', copy=TRUE);

bc.unique.tbl$`ONT_SSP.-`[is.na(bc.unique.tbl$`ONT_SSP.-`)] <-
FALSE;
bc.unique.tbl$`ONT_SSP.+`[is.na(bc.unique.tbl$`ONT_SSP.+`)] <-
FALSE;
bc.unique.tbl$`ONT_VNP.-`[is.na(bc.unique.tbl$`ONT_VNP.-`)] <-
FALSE;
bc.unique.tbl$`ONT_VNP.+`[is.na(bc.unique.tbl$`ONT_VNP.+`)] <-
FALSE;

colnames(bc.unique.tbl) <-
c('query','target','bcDir','SSPprev','SSP fwd','VNPprev','VNP fwd');

## read is considered 'valid' (for now) if at least one primer
matches
bc.valid.tbl <- filter(bc.unique.tbl, (SSPprev | VNP fwd | VNPprev |
SSP fwd));

## ideal reads have forward and reverse cDNA adapters in opposing
orientations bc.ideal.tbl <- filter(bc.unique.tbl,
((SSPprev & !SSP fwd & VNP fwd & !VNPprev) |

```

```
(!SSPrev & SSPfwd & !VNPfwd & VNPrev));
write.csv(bc.ideal.tbl, row.names=FALSE,
  file=gzfile('barcode-adapter_assignments_ideal.csv.gz'),
  quote=FALSE);
write.csv(bc.valid.tbl, row.names=FALSE,
  file=gzfile('barcode-adapter_assignments_valid.csv.gz'),
  quote=FALSE);
```

12 Create a list of used barcodes

```
zcat barcode-adapter_assignments_ideal.csv.gz | awk -F',' '{print
$2}' | \
  sort | uniq -c | awk '{if($1 > 100){print $2}}' >
used_barcodes.txt
```

13 Demultiplex valid reads (combined corrected and uncorrected) by barcodes using [fastx-fetch.pl](https://github.com/yyuan94/fastx-fetch.pl)

```
cat used_barcodes.txt | while read bc
do echo "*** ${bc} ***"
mkdir -p demultiplexed/${bc};
pv uncorrected_corrected_all.fasta.gz | \
  ~/scripts/fastx-fetch.pl -i <(zgrep ${bc} barcode-
adapter_assignments_ideal.csv.gz | awk -F',' '{print $1}')
```

gzip > demultiplexed/\${bc}/\${bc}_reads_all.fasta.gz;

done

14 Demultiplex barcode-demultiplexed reads by SSP direction.

Note that the last four values in the 'wide' table refer to the reverse and forward mappings of the SSP and VNP primers respectively). The reverse reads are reverse-complemented with [fastx-rc.pl](https://github.com/yyuan94/fastx-rc.pl), followed by a final concatenation to simplify the subsequent alignment steps.

```

cat used_barcodes.txt | while read bc
do echo "*** ${bc}/fwd ***";
pv demultiplexed/${bc}/${bc}_reads_all.fasta.gz | \
~/scripts/fastx-fetch.pl -i <(zgrep 'FALSE,TRUE,TRUE,FALSE$'
barcode-adapter_assignments_ideal.csv.gz | awk -F',' '{print $1}')
| \
gzip > demultiplexed/${bc}/${bc}_reads_fwd.fasta.gz;
echo "*** ${bc}/rev ***";
pv demultiplexed/${bc}/${bc}_reads_all.fasta.gz | \
~/scripts/fastx-fetch.pl -i <(zgrep 'TRUE,FALSE,FALSE,TRUE$'
barcode-adapter_assignments_ideal.csv.gz | awk -F',' '{print $1}')
| \
fastx-rc.pl | gzip >
demultiplexed/${bc}/${bc}_reads_rev.fasta.gz;
pv demultiplexed/${bc}/${bc}_reads_fwd.fasta.gz
demultiplexed/${bc}/${bc}_reads_rev.fasta.gz | zcat | \
gzip > demultiplexed/${bc}/${bc}_reads_dirAdjusted.fasta.gz
done

```

Transcriptome Mapping

15 Reads are mapped to the transcriptome with LAST.

The results of that mapping can be piped through *last-map-probs* to exclude unlikely hits, then through [maf_bcsplit.pl](#) to convert to a one-line-per-mapping CSV format. This CSV format is further processed to make sure that there is only one mapping per transcript-read pair, and then aggregated to sum up counts per transcript.

```

mkdir -p mapped
cat used_barcodes.txt | while read bc
do echo "*** ${bc} ***";
lastal -P 10 Mus_musculus.GRCm38.cds.all.fa <(pv
demultiplexed/${bc}/${bc}_reads_dirAdjusted.fasta.gz | zcat) | \
last-map-probs | ~/scripts/maf_bcsplit.pl | tail -n +2 | \
awk -F',' '{print $1,$2,$3}' | sort | uniq | \
awk -v "bc=${bc}" '{print bc,$2,$3}' | sort | uniq -c | gzip >
mapped/trnCounts_LAST_${bc}_vs_Mmus_transcriptome.txt.gz;
done

```

Annotation and Result generation

- 16** Transcript counts are merged with ensembl gene annotation, then converted into wide format (one line per transcript) using an R script.

The transcript annotation in this case is from ensembl BioMart (see Guidelines for more details).

```
#!/usr/bin/env Rscript
library(dplyr);
library(tidyr);

## load ensemble transcript metadata (including gene name)
ensembl.df <-
as.tbl(read.delim('ensembl_mm10_geneFeatureLocations.txt.gz',
  col.names=c('transcript','Description','Start','End',
    'Strand','Gene','Chr'),
  stringsAsFactors=FALSE));
ensembl.df$Description <- sub(' \\. *$', '', ensembl.df$Description);
ensembl.df$Description <- sub('^(\.
{50}).+$', '\\1...', ensembl.df$Description);
ensembl.df[,1:7] <- ensembl.df[,c(1,7,5,3,4,2,6)];
colnames(ensembl.df)[1:7] <- colnames(ensembl.df)
[c(1,7,5,3,4,2,6)];
options(scipen=15); ## don't show scientific notation for large
positions
## load used barcode identifiers
bcNames <- readLines('used_barcodes.txt');
## load count data into 'narrow' array (one line per count)
trn.counts <- tibble(); for(bc in bcNames){
  trn.counts <-
    bind_rows(trn.counts,
      as.tbl(read.table(

sprintf('mapped/trnCounts_LAST_%s_vs_Mmus_transcriptome.txt.gz',
bc),
      col.names=c('count','barcode','transcript','dir'),
      stringsAsFactors=FALSE)));
}

## remove revision number from transcript names (if present)
trn.counts$transcript <- sub('\\.[0-
9]+$ ', '', trn.counts$transcript);
## convert to wide format (one line per transcript)
trn.counts.wide <- spread(trn.counts, barcode, count) %>%
  mutate(dir = c('+='fwd', '-='rev')[dir]);
for(bd in colnames(trn.counts.wide[, -1])){
  trn.counts.wide[[bd]] <- replace_na(trn.counts.wide[[bd]], 0);
```

```
}  
## merge ensembl metadata with transcript counts  
gene.counts.wide <- inner_join(ensembl.df, trn.counts.wide,  
by='transcript');  
gene.counts.wide <- gene.counts.wide[order(-  
rowSums(gene.counts.wide[, -(1:8)])),];  
## write result out to a file  
write.csv(gene.counts.wide, file='wide_transcript_counts_LAST.csv',  
row.names=FALSE);
```
