ABSTRACT

Summary:

The enzyme methodology employed in this reagent is based on the reaction first described by Talke and Schubert. To shorten and simplify the assay, the calculations are based on the discovery of Tiffany, et al. that urea concentration is proportional to absorbance change over a fixed time interval. The reaction is monitored by measuring the rate of decrease in absorbance at 340 nm as NADH is converted to NAD.

MATERIALS

MATERIALS

Calibrator Fisher Diagnostics Catalog
#TR43002

Reagents Fisher Diagnostics Catalog
#TR12003

Microplate Contributed by users

Platereader Contributed by users

Keywords: Urea Protocol

1 Add 3 µl of calibrator and sample to each well.

2 Add 300 µl of reagent to each well. Incubate at 37°C for 30 seconds. Read at 340 nm.

IMPORTANT: Make sure not to add any bubbles to the wells when dispensing reagents, this will interfere with reading in the platereader.

3 Incubate at 37°C for 60 seconds. Read at 340 nm.

4 Subtract blank readings from final readings. The assay will be linear so the unknown samples can be calculated as $(\text{Sample Absorbance} \div \text{Calibrator Absorbance}) \times \text{Calibrator Concentration}$.
